

# How to scan web sites with Faraday IDE on Kali Linux

---

## Introduction

The motivation for this paper is to show the user how to quickly get Kali Linux up and running, along with Damn Vulnerable Web Application (DVWA) to use the Faraday IDE in order to scan a web site [in this case, DVWA]. Faraday is a bad-ass tool to aggregate results from numerous other tools in one place and show the total findings of vulnerabilities. Basically: “Faraday introduces a new concept – IPE (Integrated Penetration-Test Environment) a multiuser Penetration test IDE. Designed for distribution, indexation and analysis of the data generated during a security audit. The main purpose of Faraday is to re-use the available tools in the community to take advantage of them in a multiuser way.” source: <https://tools.kali.org/information-gathering/faraday>

## Requirements

If you see the following \$ symbol on a command line to execute, what that means is that the command is executed as a regular user, i.e. the Ubuntu user. Ignore the leading \$ and execute the rest of the command.

```
$ command to execute as a regular user
```

If you see a command line lead with the # symbol, then that means that the command is executed as the root user. This implies you need to elevate to the root user before running the command, e.g. with: sudo su - root.

```
# command to execute as the root user
```

## VirtualBox

Go to: <https://www.virtualbox.org/wiki/Downloads> and download VirtualBox.

The author is running on Ubuntu 17.04, so following to this URL:

[https://www.virtualbox.org/wiki/Linux\\_Downloads](https://www.virtualbox.org/wiki/Linux_Downloads)

For Ubuntu, double click on the .deb file, i.e. virtualbox-5.2\_5.2.0-118431-Ubuntu-zesty\_amd64.deb, and install VirtualBox on your local workstation.

## Clean VirtualBox Networking

Run these two commands from a Terminal:

```
VBoxManage list natnetworks  
VBoxManage list dhcpservers
```

Output:

```
NetworkName: 192.168.139-NAT  
IP: 192.168.139.1  
Network: 192.168.139.0/24
```

```

IPv6 Enabled: No
IPv6 Prefix: fd17:625c:f037:a88b::/64
DHCP Enabled: Yes
Enabled: Yes
loopback mappings (ipv4)
    127.0.0.1=2

NetworkName: 192.168.139-NAT
IP: 192.168.139.3
NetworkMask: 255.255.255.0
lowerIPAddress: 192.168.139.101
upperIPAddress: 192.168.139.254
Enabled: Yes

NetworkName: HostInterfaceNetworking-vboxnet0
IP: 172.20.0.3
NetworkMask: 255.255.255.0
lowerIPAddress: 172.20.0.101
upperIPAddress: 172.20.0.254
Enabled: Yes

NetworkName: HostInterfaceNetworking-vboxnet1
IP: 0.0.0.0
NetworkMask: 0.0.0.0
lowerIPAddress: 0.0.0.0
upperIPAddress: 0.0.0.0
Enabled: No

```

Now, delete ALL of the pre-installed VirtualBox networks (one at a time following the syntax below):

```

VBoxManage natnetwork remove --netname <NetworkName_from_above>
VBoxManage natnetwork remove --netname 192.168.139-NAT
# repeat as many times as necessary to delete all of them.

```

```

VBoxManage dhcpserver remove --netname <DHCP_Server_NetworkName_from_above>
VBoxManage dhcpserver remove --netname 192.168.139-NAT
# repeat as many times as necessary to delete all of them.

```

## Add VirtualBox Networking

Now, add the new VirtualBox networks so the Kali Linux guides work.

```

VBoxManage natnetwork add \
--netname 192.168.139-NAT \
--network "192.168.139.0/24" \
--enable --dhcp on

VBoxManage dhcpserver add \
--netname 192.168.139-NAT \
--ip 192.168.139.3 \
--lowerip 192.168.139.101 \
--upperip 192.168.139.254 \
--netmask 255.255.255.0 \
--enable

```

```

VBoxManage hostonlyif create

VBoxManage hostonlyif ipconfig vboxnet0 \
--ip 172.20.0.1 \
--netmask 255.255.255.0

VBoxManage dhcpserver add \
--ifname vboxnet0 \
--ip 172.20.0.3 \
--lowerip 172.20.0.101 \
--upperip 172.20.0.254 \
--netmask 255.255.255.0

```

```
VBoxManage dhcpserver modify \
--ifname vboxnet0 \
--enable
```

## Vagrant

Go to: <https://www.vagrantup.com/downloads.html>, follow the appropriate link to your OS and 32 or 64 bit version representing your local workstation. Download.

For Ubuntu, double click on the .deb file, i.e. `vagrant_2.0.1_x86_64.deb`, and install Vagrant on your local system.

## Kali Linux

The author highly recommends to create a directory structure that is easy to navigate and find your code. As an example, you could use something similar to:

```
 ${HOME}/Source_Code/Education/vagrant-machines/kali-linux-vm/
```

Go ahead and make this structure with the following command (inside a Terminal):

```
$ mkdir -p ${HOME}/Source_Code/Education/vagrant-machines/kali-linux-vm/
```

Inside of the `kali-linux-vm` directory, populate a new file with the exact name, "Vagrantfile". Case matters, uppercase the "V".

### Vagrantfile:

```
# -*- mode: ruby -*-
# vi: set ft=ruby :

# Vagrantfile API/syntax version.
VAGRANTFILE_API_VERSION = "2"

Vagrant.configure(VAGRANTFILE_API_VERSION) do |config|
  config.vm.box = "Sliim/kali-2017.2-amd64"
  config.vm.box_version = "1"

  # For Linux systems with the Wireless network, uncomment the line:
  config.vm.network "public_network", bridge: "wlo1", auto_config: true

  # For macbook/OSx systems, uncomment the line:
  #config.vm.network "public_network", bridge: "en0: Wi-Fi (AirPort)", auto_config: true

  config.vm.hostname = "kali-linux-vagrant"

  config.vm.provider "virtualbox" do |vb|
    vb.memory = "4096"
    vb.cpus = "3"
    vb.gui = true
    vb.customize ["modifyvm", :id, "--cpuexecutioncap", "95"]
    vb.customize ["modifyvm", :id, "--vram", "32"]
    vb.customize ["modifyvm", :id, "--accelerate3d", "on"]
    vb.customize ["modifyvm", :id, "--ostype", "Debian_64"]
    vb.customize ["modifyvm", :id, "--boot1", "dvd"]
    vb.customize ["modifyvm", :id, "--boot2", "disk"]
    vb.customize ["modifyvm", :id, "--audio", "none"]
    vb.customize ["modifyvm", :id, "--clipboard", "hosttoguest"]
```

```
vb.customize ["modifyvm", :id, "--draganddrop", "hosttoguest"]
vb.customize ["modifyvm", :id, "--paravirtprovider", "kvm"]
end
end
```

Save and write this file.

From a Terminal, change directory to:

```
$ cd ${HOME}/Source_Code/Education/vagrant-machines/kali-linux-vm/
```

Then run (inside the directory kali-linux-vm):

```
$ vagrant up
```

This will download the appropriate image and start the virtual machine.

Once running, through the VirtuaBox GUI, login as root. Password is “toor”, root backwards. Edit the following file:

```
/etc/ssh/sshd_config
```

And change the line:

```
#PermitRootLogin prohibit-password
```

To:

```
PermitRootLogin yes
```

Then restart the ssh daemon:

```
# kill -HUP $(pgrep sshd)
```

Notice, you are on a Bridged adapter, this will open the instance to allow root to ssh in with the most unsecure password in the world. Only make this change (allowing root to login via SSH) if you require root SSH access. You can change the root user’s password, which is highly recommended.

## Damn Vulnerable Web Application (DVWA)

Go ahead and make this structure with the following command (inside a Terminal):

```
$ mkdir -p ${HOME}/Source_Code/Education/vagrant-machines/dvwa-linux-vm/
```

Inside of the dvwa-linux-vm directory, populate a new file with the exact name, “Vagrantfile”. Case matters, uppercase the “V”.

**Vagrantfile:**

```
#
# setup local instance of Damn Vulnerable Web Application (DVWA):
#
# Vagrantfile API/syntax version. Don't touch unless you know what you're doing!
VAGRANTFILE_API_VERSION = "2"

Vagrant.configure(VAGRANTFILE_API_VERSION) do |config|
    # For Linux systems with the Wireless network, uncomment the line:
    config.vm.network "public_network", bridge: "wlo1", auto_config: true
```

```

# For macbook/OSx systems, uncomment the line:
#config.vm.network "public_network", bridge: "en0: Wi-Fi (AirPort)", auto_config: true

# uncomment the next line for Macbook/OSx systems, wireless :
# config.vm.network "public_network", bridge: "en0: Wi-Fi (AirPort)", auto_config: true

config.vm.provision :shell, path: "bootstrap.sh"
config.vm.hostname = "dvwa"

config.vm.provider "virtualbox" do |vb|
  vb.memory = "1024"
  vb.cpus = "2"
  vb.gui = false
  vb.customize ["modifyvm", :id, "--cpusexecutioncap", "95"]
  vb.customize ["modifyvm", :id, "--vram", "32"]
  vb.customize ["modifyvm", :id, "--accelerate3d", "on"]
  vb.customize ["modifyvm", :id, "--ostype", "Ubuntu_64"]
  vb.customize ["modifyvm", :id, "--boot1", "dvd"]
  vb.customize ["modifyvm", :id, "--boot2", "disk"]
  vb.customize ["modifyvm", :id, "--audio", "none"]
  vb.customize ["modifyvm", :id, "--clipboard", "hosttoguest"]
  vb.customize ["modifyvm", :id, "--draganddrop", "hosttoguest"]
  vb.customize ["modifyvm", :id, "--paravirtprovider", "kvm"]
end
end

```

Save and write this file.

Inside of the dvwa-linux-vm directory, populate a new file with the exact name, “bootstrap.sh”. Case matters, all lowercase.

#### **bootstrap.sh (include the shebang in your file, the `#!/usr/bin/env bash`):**

```

#!/usr/bin/env bash
PHP_FPM_PATH_INI='/etc/php/7.0/fpm/php.ini'
PHP_FPM_POOL_CONF='/etc/php/7.0/fpm/pool.d/www.conf'

sed -i '/1337/ s/charley/'${DVWA_admin_password}'/g' /var/www/html/dvwa/includes/DBMS/MySQL.php
sed -i '/pablo/ s/letmein/'${DVWA_admin_password}'/g' /var/www/html/dvwa/includes/DBMS/MySQL.php
sed -i '/smithy/ s/password/'${DVWA_admin_password}'/g' /var/www/html/dvwa/includes/DBMS/MySQL.php
}

install_base
config_mysql
install_dvwa
update_mysql_user_pws
config_php
config_nginx
Save and write this file.

```

From a Terminal, change directory to:

```
$ cd ${HOME}/Source_Code/Education/vagrant-machines/dvwa-linux-vm/
```

Then run (inside the directory dvwa-linux-vm):  
\$ **vagrant up**

You will need the IP address from the new DVWA virtual machine.

Login with:

```
$ vagrant ssh
```

Then run:

```
$ ip a
Choose the second network adapter, it should look like:

ubuntu@dvwa:~$ ip a
1: lo: <LOOPBACK,UP,LOWER_UP> mtu 65536 qdisc noqueue state UNKNOWN
group default qlen 1
    link/loopback 00:00:00:00:00:00 brd 00:00:00:00:00:00
    inet 127.0.0.1/8 scope host lo
        valid_lft forever preferred_lft forever
    inet6 ::1/128 scope host
        valid_lft forever preferred_lft forever
2: enp0s3: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc pfifo_fast
state UP group default qlen 1000
    link/ether 02:53:17:3c:de:80 brd ff:ff:ff:ff:ff:ff
    inet 10.0.2.15/24 brd 10.0.2.255 scope global enp0s3
        valid_lft forever preferred_lft forever
    inet6 fe80::53:17ff:fe3c:de80/64 scope link
        valid_lft forever preferred_lft forever
3: enp0s8: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc pfifo_fast
state UP group default qlen 1000
    link/ether 08:00:27:f0:77:2d brd ff:ff:ff:ff:ff:ff
    inet 172.20.156.76/24 brd 172.20.156.255 scope global enp0s8
        valid_lft forever preferred_lft forever
    inet6 fe80::a00:27ff:fef0:772d/64 scope link
        valid_lft forever preferred_lft forever
```

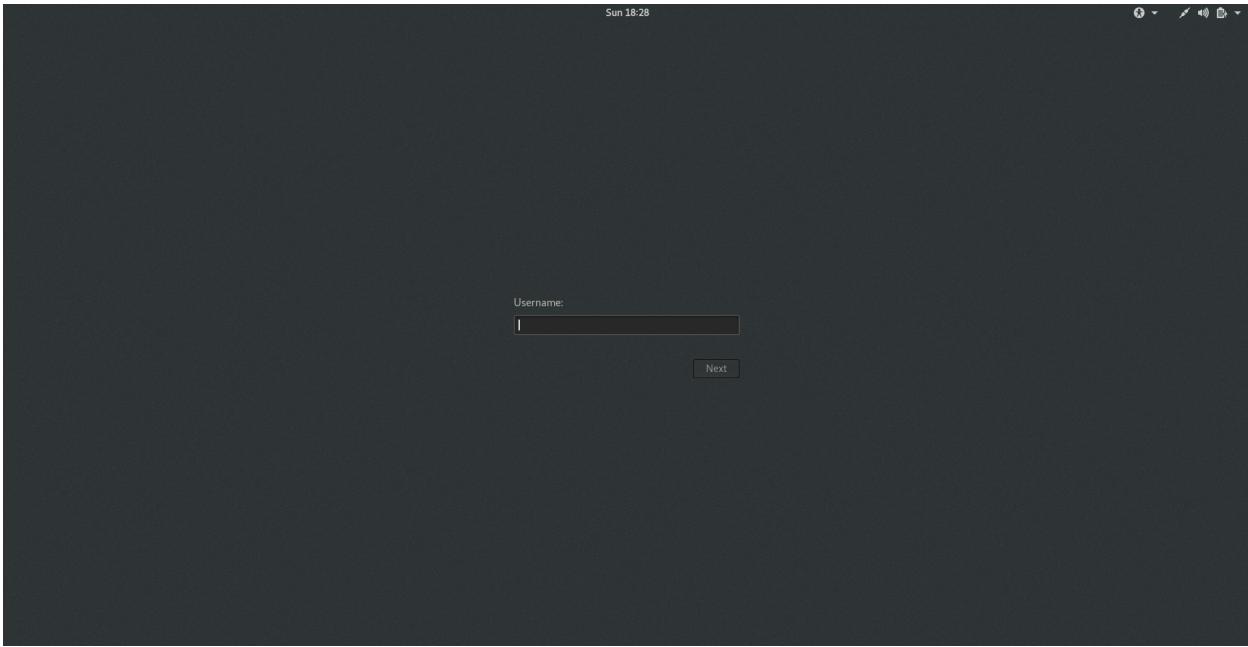

The author's home wireless network uses 172.20.156.0/24 as the network range. Therefore, the adapter, enp0s8 is what he is looking for. The IP to use as a target is 172.20.156.76. Write down your value.

## Faraday IDE (Kali Linux version)

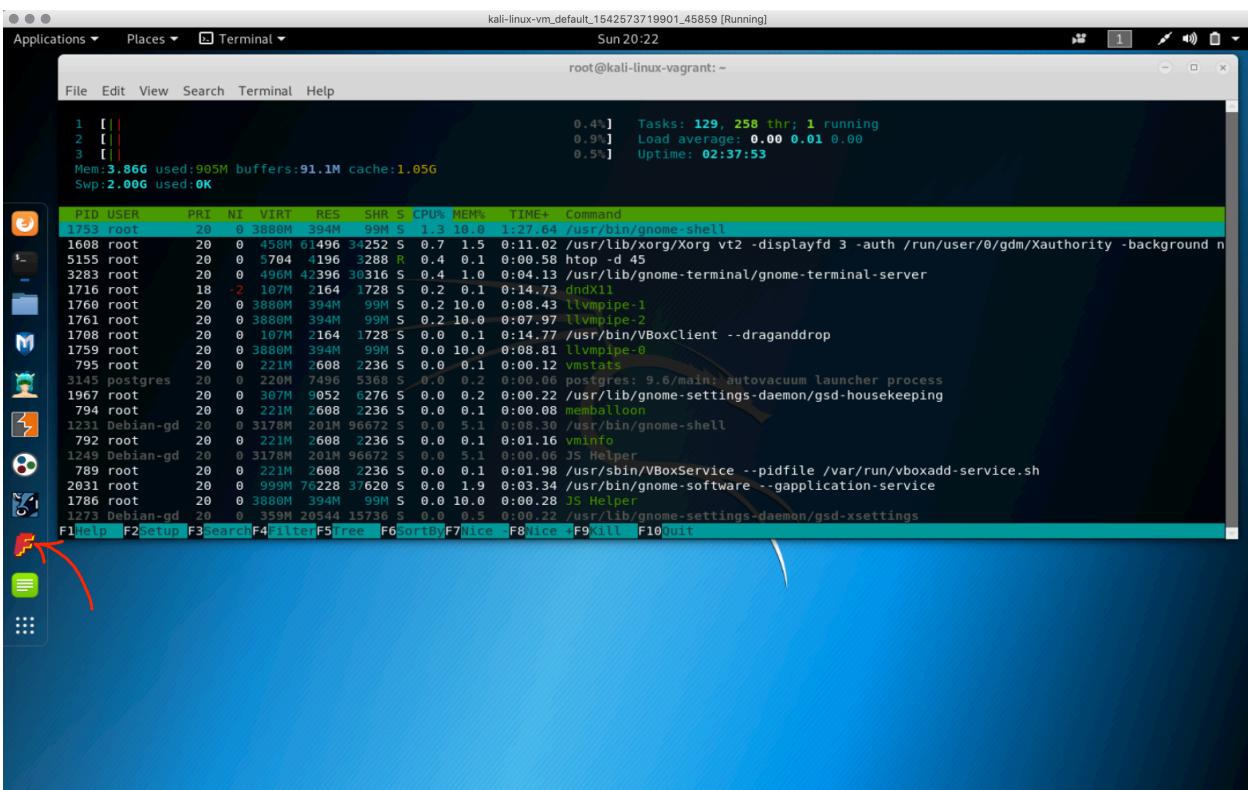

First launch both Vagrant boxes for Kali-Linux and DVWA.

For attack sequence, you can simple copy and paste out of the Appendix section in the right order. Change the ip 192.168.139.30 to your IP for your DVWA instance.

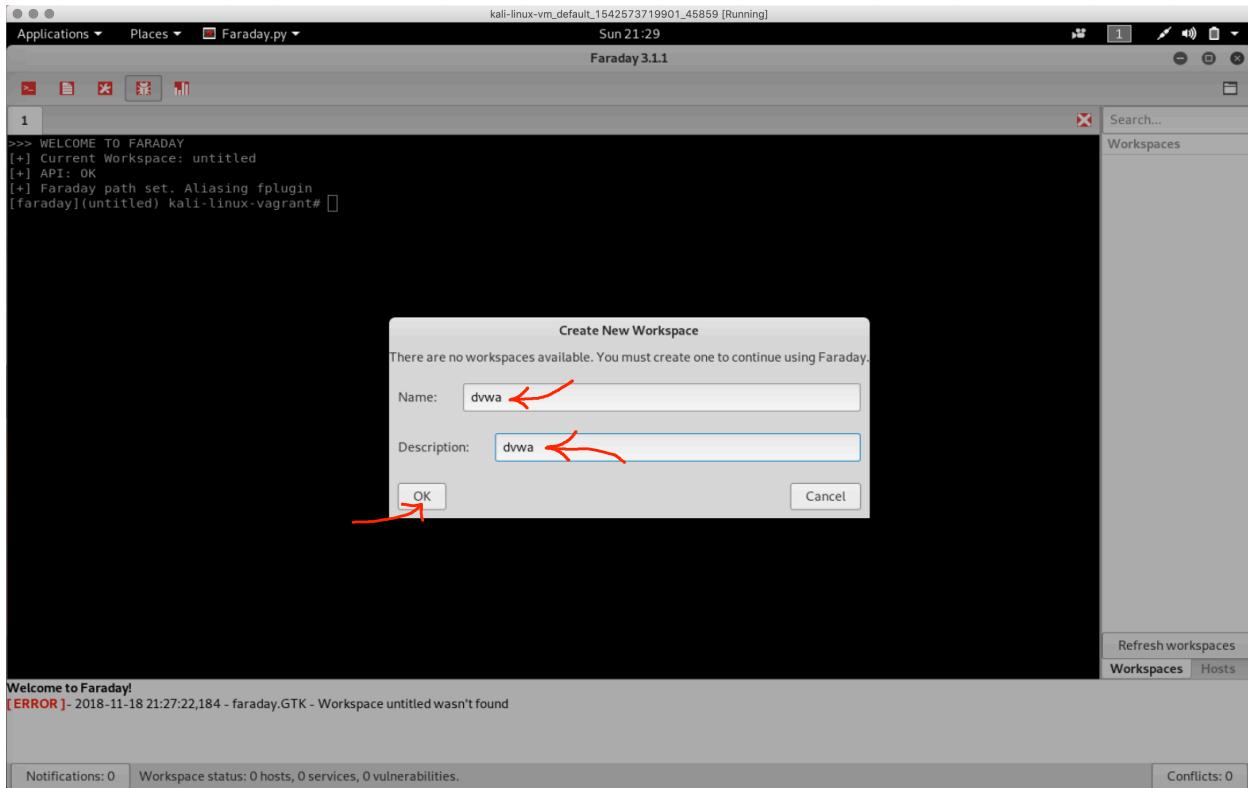

Then log into Kali-Linux with username: root and password: toor.

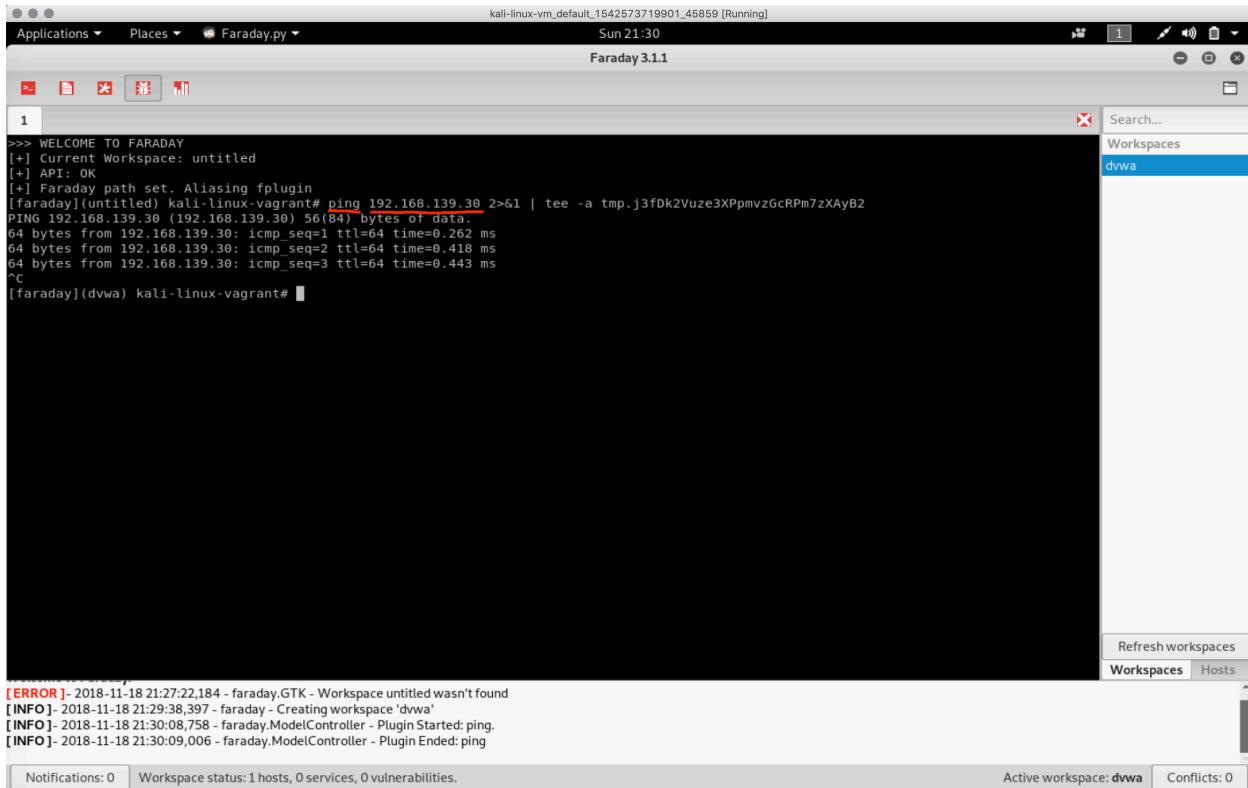

Next, from the left toolbar, open the application Faraday IDE (it has the giant letter F).

Type in “dvwa” for both fields and click on “Ok”.

In the console/terminal, type in: `ping 192.168.139.30`

Type in: `amap -bqv 192.168.139.30 22` then `amap -bqv 192.168.139.30 80`.

The screenshot shows the Faraday 3.1.1 interface running on a Kali Linux VM. The terminal window displays the output of two amap commands:

```
kali-linux-vm_default_1542573719901_45859 [Running]
Sun 21:31

Now, click on the upper left red button that looks like graphs.

This opens a web page with some good information.

Click on the Chart icon on the left. Here we see more about the vulnerabilities.

The screenshot shows a Firefox browser window titled "Status Report | Faraday - Mozilla Firefox" with the URL "localhost:5985/#/status/ws/dvwa/search?type=VulnerabilityWeb". The page displays a table of vulnerabilities found during a scan of the DVWA target. A red arrow points to the chart icon in the sidebar on the left.

SEV	NAME	SERVICE	HOSTNAMES	TARGET	DESC	ID	DATE	STA

## **Conclusion**

By following this guide, the user has installed VirtualBox, Vagrant, Kali-Linux, DVWA and ran multiple vulnerability tests/checks against the DVWA instance. All isolated on the local system. The older version of Faraday had financials tied in with the report so that a person could quantify the cost of having 'n' number of vulnerabilities within an organization. Somehow that went away with the new free version. My guess is the company wants you to pay for a license.

If you are in a job that requires Pen Testing, the author highly recommends testing out Faraday IDE. If your team needs to have multiple people sync up their findings and share outcomes, then pay for the license at: <https://www.faradaysec.com/>

The author does not get paid nor any endorsements from any site. These recommendations are from his 20 years of experience (and bias) in the IT field.

The author truly hopes you enjoyed this guide. He had a blast writing it and learning more about Faraday IDE in depth.

## Appendix

Commands reference:

Get latest vulnerabilities:

```
cd /root/.faraday/data/
wget http://cve.mitre.org/data/downloads/allitems.csv.gz
gunzip allitems.csv.gz
mv allitem.csv cwe.csv
```

Import those vulnerabilities:

```
cd /usr/share/python-faraday/
python2 ./bin/fplugin -username masterf \
--password faraday -w dvwa import_csv \
--csv /root/.faraday/data/cwe.csv
```

Ping target:

```
ping 192.168.139.30
```

Run amap against SSH and HTTPD services:

```
amap -bqv 192.168.139.30 22
amap -bqv 192.168.139.30 80
```

Run nmap against everything:

```
nmap -A -T4 -sT -p "*" -O --osscan-guess -sV --version-trace \
--max-retries 3 192.168.139.30
```

I'm totally loving dirb. Two popular checks:

```
dirb http://192.168.139.30/ \
/usr/share/wordlists/dirb/common.txt -u admin:admin

dirb http://192.168.139.30/ \
/usr/share/dirb/wordlists/vulns/apache.txt
```

Test the site with sqlmap. TODO, run a better check than forumaction=search.

```
sqlmap -u "http://192.168.139.30/?p=1&forumaction=search" --dbs
```
